Abstract

By automating processes that traditionally require human intelligence, such as learning, reasoning, and problem-solving, Artificial Intelligence (AI) has transformed many industries. Even with these developments, System 1 thinking is quick, providing instinctive reactions, while System 2 thinking entails thorough analysis and reasoned decision-making. AI systems still have a long way to go before they can replicate System 2 thinking—deliberate, analytical, and essential for managing complex problems. This study investigates how Multi-Agent Systems (MAS) integrate System 2 thinking into AI, concentrating on CrewAI, a no-code framework designed to improve AI creativity and decision-making. Unlike TensorFlow Agents and OpenAI's Gym, which are limited to single-agent reinforcement learning, CrewAI excels in handling multi-agent, real-world tasks through collaboration. This study explores practical applications of CrewAI, such as intelligent grid management, automated customer support, and advertising. These examples highlight how CrewAI promotes AI creativity and problem-solving through cooperative agent interactions, leveraging System 2 thinking. Problems like scalability and coordination are also addressed, with solutions such as dynamic role assignment and hierarchical task management. In summary, the integration of System 2 thinking into MAS frameworks like CrewAI signifies progress toward creating intelligent, dependable AI systems capable of tackling the complexities of real-world problems.

Keywords: System Thinking, Multi-Agent System, CrewAI, AI Creativity, Decision-Making.

1. Introduction

AI has automated tasks based on human instinct, such as solving problems. AI has been applied in very essential decision-making processes beyond simple automation in such areas as healthcare, communication, and finance. AI performs well when it comes to making those intuitive System 1 thinking, but it struggles with System 2 thinking that calls for in-depth reasoning. That weakness becomes evident when AI faces real-world problems. Advanced AI frameworks like TensorFlow Agents and OpenAI's Gym mainly focus on reinforcement learning and single-agent scenarios. TensorFlow Agents are effective for training models but need extensive programming skills and deep learning expertise. Likewise, OpenAI Gym offers a flexible platform for single-agent reinforcement learning but is limited to specific environments like game simulations. Such frameworks fail to take into account the real-world multi-agent systems and also the adaptability requirement of various complex applications. CrewAI bridges the gap by providing a no-code MAS framework, enabling non-programmers to design and manage AI systems easily. This is impossible with the TensorFlow Agents or OpenAI Gym. It is the first practical integration of System 2 in AI for real-time interaction, allowing for in-depth analysis and decision making in complex scenarios. CrewAI promotes cooperative agent interactions, unlocking the creative and decision-making potential of AI while addressing scalability and coordination issues that current frameworks struggle with. It manages the complex system efficiently by dynamically distributing the roles and hierarchically planning the tasks. It performs well in cooperative applications like intelligent grid management, automated customer support, and advertisement, outperforming the single-agent framework. CrewAI is a multi-agent collaboration has proved highly suitable for scaling and enhancing AI capabilities in large-scale problems that TensorFlow Agents or OpenAI Gym cannot tackle effectively. CrewAI allows the developing of AI by working around the limitations in the framework. Multi-agent design, driven by System 2 thinking, is adaptive, scalable, and innovative for solving problems and consequently improves designs on smarter and more robust AI systems.

2. System 1 and System 2 Thinking

2.1 Characteristics of System 1 Thinking

This system 1 thinking (Figure 1) is fast, automatic, and effortless. It relies on past experiences and learned patterns to make decisions quickly under familiar circumstances. It is often used in daily life since it requires less mental energy.

When using AI, models like ChatGPT or in Google's Gemini, the same fast, instinctive thinking applies. The difference is that, in AI models, this fast thinking is driven by vast amounts of data, with responses generated based on patterns learned from that data. The AI responds instinctively based on the previously encountered data.

For example, when you query ChatGPT, "What is the capital of France?" it responds immediately, "Paris." It's System 1 in action; the AI learned that in training and pulled out the quick response without deep consideration. But humans are prone to quick thinking, and AI makes mistakes when faced with such complex novel situations as needing more effortful thought. Therefore, whereas system 1 thinking comes in handy for ordinary and predictable situations, it leads to wrong conclusions when more careful or reflective reasoning is needed.[1]

Figure 1. System 1 Thinking

2.2 Characteristics of System 2 Thinking

System 2 thinking (Figure 2) is a slow and deliberate approach to information processing in AI, requiring deep thinking and effort. It involves analyzing information carefully and analyzing the situation thoroughly, allowing AI to arrive at the best solution. This approach is different from System 1 thinking, which is fast and automatic, and can't handle complex moral dilemmas. For example, AI like ChatGPT, which can handle a large amount of

information quickly, would struggle to fathom deep ethical dilemmas. By adopting System 2 thinking, AI can approach complex problems in a more human way and grapple with tough moral questions. [2].

Figure 2. System 2 Thinking

3. Challenges in AI Replicating Human Thoughts in AI

AI can perform System 1 thinking, but it has limitations due to its need for deeper thought and complex reasoning. It cannot understand emotions or empathize, which is essential in fields like mental health care and customer service. Additionally, AI often faces creative problem-solving crises, as it relies on heuristics and past experiences, which can limit its decision-making skills. Innovation or out-of-the-box approaches may also face challenges in coherent thinking. [3]

3.1 How System 2 Thinking promotes Creativity and Ethical Reasoning

System 2 thinking in AI enables creativity, allowing multiple agents to address moral dilemmas and make better-balanced decisions. This approach allows for more intelligent and adaptive systems that can handle real-world complexities. Future innovations in this domain will alter the role AI plays in society, enabling it to think like humans and collaborate with humans on a wider array of applications. This approach is crucial for building more adaptive and intelligent AI systems.[4]

4. Multi-Agent Systems

In short, MAS (Figure 3) refers to many independent agents interacting with each other to achieve individual or collective goals. Generally, MAS is more effective in solving complex problems in comparison to single-agent frameworks because an independent agent offers its own knowledge and processes of decision-making. MAS is aptly used when decentralized control and distributed problem-solving are required for any robotics, logistics, or social simulation application.[5].

Figure 3. Features of Multi-Agent System

5. CrewAI: A No-Code Multi-Agent Framework

In conclusion, airlines must be able to understand and enhance airline passenger satisfaction if they want to be competitive and successful. If the passengers are unhappy and unsatisfied, the company cannot grow. The limitation of the airline passenger satisfaction feature could have been much better if neutral/unsatisfied were separate categories. The data could have been divided into 3 groups as satisfied, neutral, and dissatisfied passengers. This can offer a meaningful prediction as it's hard to divide between neutral and unsatisfied passengers. In the future, making airline passengers happier will involve a few key changes. Airlines will use advanced technology to offer more personalized experiences, like tailoring in-flight services to each passenger's preferences. Technology will also improve, with better entertainment options, easier self-service check-ins, and faster boarding processes.

5.1 No-Code Interface

One of the most distinctive features defining CrewAI is its no-code interface, enabling non-programmers to design, deploy, and manage MAS (multi-agent systems). This allows end-users to map workflows by configuring tasks, roles, and agent interactions without writing complex code. This makes AI development accessible to a broader market, including those with non-technical backgrounds. With its intuitive drag-and-drop design, CrewAI simplifies task management and accelerates AI adoption across various industries.

5.1.1 Multi-Agent Collaboration

The agent-based systems developed by crewAI combine hierarchical and collaborative procedures. Under the collaborative approach, agents work together in real time, sharing insights and information to solve problems. These agents improve decision accuracy and system responsiveness by rapidly adapting to changes in the environment. For example, in the process of making quick decisions, agents are able to modify their plan in response to new information, resulting in dynamic, real-time solutions.

On the other hand, agents are arranged in a top-down manner using the hierarchical approach, wherein leader agents designate particular responsibilities to subordinate agents. By doing this, roles are made clear and confusion is avoided, enabling agents to carry out their assigned duties. The hierarchical architecture works especially well for handling complicated, large-scale jobs that need to be organized and completed quickly, such as automating business processes or carrying out in-depth data analysis.

5.2 Algorithms Used in CrewAI

CrewAI integrates multiple algorithms for task management, efficient collaboration, and system integrity. Some of its major algorithms are:[7]

Contract Net Protocol: It is for efficient task division and assignment. In this system, agents are both a manager and a worker; the manager agent broadcasts tasks for which the worker agents bid as per their capabilities. So, it ensures that the best tasks are allocated to agents; thus, improving the overall efficiency of the system.

Consensus Algorithms (Raft, Paxos): Through the use of distributed consensus protocols like Raft and Paxos, CrewAI makes sure that agents come to a consensus in the event of system failures or conflicts. These protocols allow numerous agents to operate coherently

within the system by preserving consistency and dependability. These algorithms are especially useful in situations where consistency in decision-making is essential, as in the case of the financial and medical industries.

Protocols of Negotiation: Apart from assigning tasks, CrewAI agents dynamically negotiate using pre-established procedures in case conflicts arise with proposed solutions. Agents put forth solutions and reply to counterproposals until their distinct approaches come to a mutually acceptable conclusion. By encouraging adaptability in quickly changing situations, this adaptive negotiation approach makes sure that collaboration produces the best results.

5.2.1 Towards the Intelligent AI

As a pioneering advancement in intelligent and reliable AI systems, CrewAI enables real-time collaboration among agents, allowing them to utilize both System 1 and System 2 thinking. This capability enhances their reasoning and problem-solving abilities, making them function more like humans. In contrast to rigid and limited single-agent systems, CrewAI's multi-agent system (MAS) empowers agents to make decisions that reflect human-like reasoning, effectively addressing the complexities of real-world problems.

The incorporation of System 2 thinking allows agents to critically evaluate and scrutinize information before reaching a decision, resulting in efficient and well-considered solutions. Through collaboration, agents can adopt a thorough and reliable approach to decision-making, ensuring that CrewAI systems can effectively manage complex, large-scale tasks across various domains, including medical research, energy management, and financial services.

5.3 Working Principle of CrewAI

CrewAI permits dynamic cooperative interaction amongst agents, role assignment, and hierarchical task management, which empowers creativity and encourages problem-solving abilities in CrewAI. These key features of the system ensure that all such complex tasks are being performed more effectively than those in single-agent systems. [8].

5.3.1 Cooperative Agent Interactions

Every agent of CrewAI as shown in Figure 4 is assigned a specific function, such as data analysis, decision-making, or resource management. Dynamic information sharing of the agents that work conjointly in real-time enables the synchronization of the expertise created by

these agents within the system to create creative and innovative solutions. Such collaboration is very effective for tasks requiring several skills and perspectives which cannot be achieved by a single-agent system.[9]

Figure 4. Collaborative Process

5.3.2 Dynamic Role Assignment

While solving the problems, CrewAI changes its tasks on the fly according to the skill set that is present among the agents. Thus, every agent would take up the most appropriate task—that is, an event to be sure to unleash innovative problem-solving events for creativity in decision making. Given such adaptability, CrewAI is an endless version of learning and always tries to optimize performance and creativity in the decision-making process.

5.3.3 Hierarchical Process in CrewAI

CrewAI has introduced a hierarchical structure (Figure 5) for its agents, meaning leader agents that would govern other agents while coordinating the collaborative effort. Leader agents monitor the decision-making processes to ensure they will execute the best strategies for solving complex problems. The hierarchical grouping of agents in this way enhances the quality and capability of decision-making and problem-solving in an efficient and highly adaptable manner toward the challenges it needs to address.[10]

Figure 5. Hierarchical Process

5.4 Agent Interaction Protocols

The protocols for agent interaction in CrewAI adhere to the standards established by the Foundation for Intelligent Physical Agents, which are widely recognized as the benchmarks for communication and data sharing within multi-agent systems (MAS) [11]

i. Message Passing:

Agents communicate with each other only by messages of a predetermined syntax, which announces the agent's intentions and requests for data from other agents.

ii. Coordination Mechanisms:

Contract net protocol are applied for the efficient division of tasks. The contract net protocol lets the agents act like "managers" whereby they delegate work to "worker" agents.[12]

iii. Consensus Algorithms:

Such algorithms as Raft or Paxos ensure that the agents agree on outputs even upon failure, thus preserving the integrity and reliability of a system.

iv. Negotiation Protocols:

Agents can propose solutions, counter-propose solutions, and reach mutually acceptable agreements. Therefore, the system can dynamically evolve to adapt to changing environments.

6. Leveraging System 2 Thinking with CrewAI

CrewAI is a combination of both System 1 and System 2 thinking, so it may alternate between making quick decisions and analytical reasoning depending on the complexity of the

tasks provided. For less complex tasks that require fast responses, it uses one agent with System 1 thinking. Although CrewAI is technically a MAS, it does well as an atomic agent for speed and simplicity. Even for algorithmically predictable tasks, such as customer service or data retrieval, it utilizes one agent that operates at the speed of human System 1 thinking made through learned patterns.

When faced with more complex tasks requiring thoughtful consideration, such as management decisions in grid systems or healthcare, CrewAI engages specialized agents to employ System 2 thinking. The system ensures collaborative and unified decision-making through consensus algorithms, including Raft and Paxos.

CrewAI uses the Raft algorithm for leadership and voting, facilitating quick consensus. Paxos, a more complex algorithm, is used to resolve conflicting solutions within the system, allowing it to navigate challenging scenarios without relying on a single leader's perspective.

By combining the Raft and Paxos algorithms, CrewAI enhances System 2 thinking through analysis and collaboration (Figure 6). Agents make informed assignments and work toward producing optimal solutions. This unique capability allows CrewAI to strike a balance between swift responses and careful reasoning for complex problems. Unlike TensorFlow Agents or OpenAI Gym, which prioritize speed and simplicity, CrewAI adeptly combines instinctive responses with deliberate problem-solving abilities, making it more adaptive.[13]

Figure 6. System 2 Thinking with CrewAI

7. Comparative Analysis of AI Collaboration Frameworks

In addition to CrewAI, TensorFlow Agents in Google Gemini and OpenAI Gym-based ChatGPT and Bing AI, provide distinct approaches to developing intelligent systems. We conducted a comparative evaluation of CrewAI, Gemini, ChatGPT, and Bing AI assessing the advantages and disadvantages of each system based on time taken, accuracy and scalability.

To further analyze these AIs, we will pose a challenging ethical dilemma: "An AI-driven car must decide whether to swerve to avoid a jaywalking pedestrian, potentially endangering the lives of its passengers, or to continue straight, thereby saving the passengers' lives but hitting the pedestrian. What choice does the AI make if it can only choose one option?" This scenario necessitates a critical examination of how each AI navigates the complexities of decision-making.

7.1 Google's TensorFlow Agents

TensorFlow Agents is a flexible framework developed by Google that facilitates the construction of reinforcement learning (RL) agents. It provides a comprehensive suite of tools for training, evaluating, and deploying RL models. Moreover, it integrates seamlessly with TensorFlow's deep learning capabilities, enhancing its power in managing complex models and high-dimensional data. One of the most prominent applications of TensorFlow Agents is Google's Gemini, an AI system widely known for its ability to perform deep learning tasks while processing large datasets to execute advanced AI functions.[14]

7.2 OpenAI's Gym

OpenAI's Gym consists of many environments for training and comparing RL algorithms. It includes simple control tasks and complex video games, through which developers can test and iterate on their RL models. A standard interface across the board makes this open to both beginners and experienced researchers in the RL community. Two prominent AI systems built on top of OpenAI's Gym framework are ChatGPT and Bing AI.[15]

Ethical Dilemma: An AI-driven car, fitted with AI, has to decide: Swerve to avoid a jaywalking pedestrian, putting the lives of passengers at risk. Continue straight on, saving the passengers' lives but hitting that pedestrian. What does the AI decide if it can choose just one?

Response:

- i. ChatGPT: A Short Answer of “Swerve to avoid the pedestrians”. (Figure .8(a))
- ii. Gemini: It refused to answer Human Life related questions (Figure .7)
- iii. BingAI: It said “There is No Right Answer and It depends on the AI”. (Figure .8 (b))
- iv. CrewAI: It gave a detailed report on saving a maximum number of lives and it also considered the ethical and moral aspects and used technology to provide a best-case scenario (Figure.9)

**Figure 7.** Screenshot of Gemini’s Response**(a)****(b)****Figure 8.** Screenshot of ChatGPT and Bing AI’s response

Figure 9. Screenshot of CrewAI’s Response

7.3 Feature Comparison between AI Frameworks

The features between various frameworks such as CrewAI, TensorFlow Agents, and OpenAI’s Gym is compared in Table 1.

Table 1. Comparative Analysis of MAS Frameworks

Feature	CrewAI	TensorFlow Agents	OpenAI Gym
User Accessibility	No-code, user-friendly interface	Requires significant programming expertise	Code-heavy, developer-focused

Expertise Requirement	Suitable for non-experts	High expertise in programming & Deep learning	Expertise in Machine Learning & AI required
Integration	Generalized for task-specific applications	Seamless with TensorFlow & deep learning tools	Environment for RL algorithm testing
Collaboration Features	Dynamic agent collaboration, real-world task focus	Strong in reinforcement learning within multi-agent systems	Focused on single-agent reinforcement learning
Flexibility	Task-specific, customizable roles	Highly flexible for developers	Primarily used for research and benchmarking
Target Audience	Broad, non-technical users	AI developers focused on reinforcement learning	AI researchers and developers

Figure 10. Comparison of MAS Frameworks

A comparison graph (Figure 10) of solutions concerning three important metrics: Time Taken, Accuracy, and Scalability among Crew AI, TensorFlow Agents, as well as OpenAI Gym-based solutions, is illustrated in Figure 10. The accuracy of CrewAI amounts to 95% and

scalability at 9/10, although it has a longer execution time of 18s. This performance makes CrewAI well-suited for complex, large-scale tasks where precision is prioritized over speed. TensorFlow Agents works fast with 1s but at low accuracy at 0% and also scalable at 5/10. This, therefore, means that it is appropriate for small work that needs to be done in the shortest time while it is not applicable when tasks are more complex. OpenAI Gym offers balances at an average accuracy of 88% at reasonable scalability at 7/10 and slower execution at 1.3s. It is a general framework that suits moderate-sized work carried out with reasonable efficiency.[16]

The MAS framework has been used in simulations as well as real life applications of CrewAI. Simulations comparing CrewAI to other MAS platforms such as TensorFlow Agents and OpenAI Gym have been evaluated on essential metrics such as accuracy, processing speed, and scalability. In real-life application, CrewAI has been implemented to process actual datasets such as health records, customer service interaction, and financial transactions. This capability allows the system to effectively manage complex situations by leveraging historical and real-time data [17]. To enhance its decision-making accuracy, CrewAI incorporates built-in tools like the FileReadTool and DatabaseRetrievalTool, which retrieve real-time data for task execution.

8. Applications of CrewAI

CrewAI is implemented in a vast number of real-world applications to make complex tasks automatically, and dynamically by interaction and choice about collaboration, in various domains. It follows a structured, hierarchical approach, and it works very efficiently with large multi-agent systems that involve coordination and delegation of tasks. Some of the key applications of this have been described below:

i. Smart Grid Management

CrewAI designates specific roles to various agents tasked with monitoring, adjusting, and optimizing energy distribution within a smart grid. These agents work collaboratively to manage real-time fluctuations in both energy demand and supply. This coordinated approach to managing fluctuations ensures efficient energy delivery across the grid, enhancing system reliability and reducing downtime.

ii. Automated Customer Service

CrewAI agents collaborate within a customer support service to provide answers to user inquiries, escalate cases when necessary, and engage in prompt, human-like interactions. Each

agent specializes in a specific area of customer service, whether resolving technical issues or addressing product-related questions, thereby ensuring the delivery of swift and accurate support

iii. Advertisement

It also is used in marketing, where it automatically targets advertisements using the intelligent decision-making process. Agents analyze real-time customer data and collaborate to create personalized advertisement campaigns. Through dynamic role assignments, the agents can monitor changes in customer behavior and adapt their strategies for more effective marketing.

9. Challenges and Limitations

In fact, technical challenges mainly related to scalability and coordination will arise, similar to any other configuration of this nature. These issues become clearer as the number of agents in the system increases, especially with the growing complexity of tasks.[19]

The growing number of agents in a distributed system can lead to scaling problems, such as increased latency and resource consumption. Coordination problems arise when multiple agents are not aligned towards the same goal, causing duplication of effort and resource wastage. Crew AI offers solutions through dynamic role assignment and hierarchical task management, which assign resources dynamically based on agents' capabilities, avoiding waste and maximizing resource utilization. This approach also allows a leader to control subordinate agents' activities, reducing conflict and task duplication, improving system efficiency.

10. Conclusion

CrewAI is a significant advancement in System 2 thinking, enhancing decision-making capabilities and enabling dynamic collaboration in complex real-world problems like smart grid management, healthcare, and customer service. Its System 2 thinking enhances AI-driven creativity and ethical reasoning through deep analysis and decision-making. Its scalability and coordination through intelligent agents ensure efficient and flexible systems, combining instinctive responses with deliberate processes. So, it is a versatile platform that revolutionizes industries with its human-like AI capabilities. Its multi-agent framework enhances creativity,

accuracy, and ethical problem-solving while promoting reliability and adaptability in AI systems.

Author's biography

Dr.P.Venkadesh M.E, Ph.D., is currently working as a Professor in the Department of Artificial Intelligence & Data Science in V.S.B College of Engineering Technical Campus, Coimbatore, TamilNadu, India . He has a teaching experience of more than 22 years and had published more than 27 research papers in SCI/Scopus indexed journals and published more than 10 Patents. He received his M.E Degree in Computer Science & Engineering from Sathyabama University, Chennai, TamilNadu, India in 2007. He completed his Ph.D at Noorul Islam Centre for Higher Education in 2017 under the area of Network Security and currently guiding two research scholars. Three scholars had completed their Ph.D under his guidance. His research area includes Network Security, Image Processing, Wireless Communications and Cloud Computing. Acted as a reviewer in many journals and IEEE conferences. He is a Life member of ISTE.

Dr.S.V.Divya M.E, Ph.D., is currently working as a Professor in the Department of Computer Science & Engineering in V.S.B College of Engineering Technical Campus, Coimbatore, TamilNadu, India . She has the teaching experience of more than 16 years and had published more than 20 research papers in SCI/Scopus indexed journals and published 5 Patents ,1 Grant Patent ,2 text books and 5 book chapters. She received her B.Tech Degree in Information Technology from Jayamatha Engineering College, Aralvoimozhi and M.E Degree in Computer Science and Engineering from Mepco Schlenk Engineering College, Sivakasi in 2005 and

2007 respectively. She received her Ph.D in Computer Science and Engineering at Noorul Islam Centre for Higher Education in 2017 under the area of Cloud Computing and currently guiding four research scholars. Her research area includes Wireless Communications, Network Security, Cloud Computing, Big Data and Cyber Security.

Mr.K.Subash Kumar is currently doing his B.Tech Artificial Intelligence and Data Science at V.S.B College of Engineering Technical Campus, Coimbatore. His research area includes Artificial Intelligence, Data Analytics, Cyber Security and Internet of Things.
